Main things we care about: derivetives, Taylor expansions, some single variable integrals, ... multiple integrals aren't so useful for us.

Note: the multivariable calculus you learned probably built up to Stokes theorem etc. These things are important for physics, less so for optimization. Les ned to be able to take derivatives of multivariable functions and reason about the behavior of these functions. You may have done this in IRZ and IRS, maybe saw a bit of R". So let's neview and build up the material you reed.

First, recall the def'n of the ordinary derivative of a single-named function of a real variable, which we may write:  $f: \mathbb{R} \to \mathbb{R}$ , i.e. y=5(x);

$$f(x) = \frac{d\xi}{dx} = \lim_{n \to \infty} \frac{f(x+n) - f(x)}{h}$$

Partial derivatives are just prolingly derivatives applied to a gingle veriable of a multiple variable function  $f: \mathbb{R}^n \to \mathbb{R}$  with the remaining arguments held constant;

$$\frac{\partial s}{\partial x_i} = \lim_{h \to 0} \frac{s(x_1, \dots, x_{i-1}, x_i + h, x_{i+1}, \dots, x_n) - s(x_1, \dots, x_n)}{h}$$

Most important for us is the gradient  $\nabla S$  (" $\nabla$ " is pronounced "nabla" or "del" or "grad"), which is the vector in  $\mathbb{R}^n$  which is the alrection and made of steepest increase in 5 at a point x, How can we recover the well-known expression for DF: (2)

$$95 = \left(\frac{95}{3x_1}, \dots, \frac{35}{3x_n}\right) \in \mathbb{R}^n$$

from this verbal description of the grandient? Let's consider. finding or that solves:

maximize & d S(x+tv) took,

That is, we restrict & to lines passing through k, take the ordinary devinative of the resulting single-variable function of t, and try to find the vector  $V \in \mathbb{R}^{n}$  which maximizes the vote of charge real Note: (s.t.  $||v||_2 = 1$ )

$$\frac{d}{dt} S(x+tv) \Big|_{t=0} = \left( \sum_{i=1}^{m} v_i \frac{\partial S}{\partial x_i} \Big|_{x+tv} \right) \Big|_{t=0}$$

$$= v_i \frac{\partial S}{\partial x_i} + \dots + v_n \frac{\partial S}{\partial x_n}.$$

Among all VER" S.t. //V/12 = 1, the one which maximizes this quantity is:

$$V = \frac{\left(\frac{3\xi_{1}}{3\xi_{1}} + \dots + \frac{3\xi_{n}}{3\xi_{n}}\right)}{\left(\frac{3\xi_{1}}{3\xi_{1}} + \dots + \frac{3\xi_{n}}{3\xi_{n}}\right)}.$$

Marrian we can see that this is true by using the Cauchy - Schoerz inequality:

$$\left| \frac{d}{dt} \left\{ \left( x_{t} + v_{t} \right) \right|_{t=0} \right| = \left| v_{t} \frac{\partial f}{\partial x_{t}} + \cdots + v_{n} \frac{\partial f}{\partial x_{n}} \right|$$

$$\leq \left| \left( v_{t}, \ldots, v_{n} \right) \right|_{2} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0} \cdot \left| \left( \frac{\partial f}{\partial x_{t}}, \cdots, \frac{\partial f}{\partial x_{n}} \right) \right|_{t=0}$$

We know in the C-S inequality that this inequality is obtained when  $(v_1,...,v_n)$  is linearly dependent on  $(\frac{\delta^3}{\delta x_1},...,\frac{\delta \xi}{\delta x_n})$ . Since the magnitude of  $(v_1,...,v_n)$  is restricted to be equal to 1, the choice is clear.

Hence, v is the vector which points in the direction of steepest increase by definition. We can also now see that that direction is:

$$\Delta \xi = \left(\frac{\partial x^{1/2}}{\partial z}, \frac{\partial x^{2/2}}{\partial z}\right)^{1/2}$$

i.e. the gradient of 5, and that the slope there (or, the vate of increase) is just 117511.

The next differential operator to look at is the Lacobian:

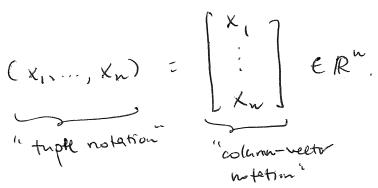

$$DS = \begin{cases} \frac{\partial S_1}{\partial x_1} & \frac{\partial S_2}{\partial x_n} \\ \frac{\partial S_m}{\partial x_1} & \frac{\partial S_m}{\partial x_n} \end{cases} \in \mathbb{R}^{m \times m},$$

where from Rm - it is a map from Rm to Rn - it is a vector-valued function of multiple veriables. We can write fine terms of its component functions:

Each now of Dis is the transpose of the gradient of a component function. Note also that if  $g: \mathbb{R}^n \to \mathbb{R}$  is a scalar-valued function, then:

$$\nabla g = \left(\frac{\partial g}{\partial x_1}, \dots, \frac{\partial g}{\partial x_n}\right) = \left[\frac{\partial g}{\partial x_1}, \dots, \frac{\partial g}{\partial x_n}\right]^T = Dg.$$

that is, the gradient of a scalar-field is the transpose of its Jacobian. Note carefully that we use two notations for vectors in R":

It is important to differentiate between vow and column vectors, since they correspond to different geometric objects. A column vector, by our identification with IRn above, is the usual vector, by our identification with IRn above, is the usual geometric vector—it is an "arrow" in IRn, with a direction and magnitude we can write the polar representation of a vector as:

$$x = ||x|| \cdot \frac{x}{||x||} \in \mathbb{R}^{+}$$
.

magnitude direction

On the other hand, a now vector is better thought of as a linear map, i.e. as a function. E.g., for a EIR's, we have the mapping:

$$x \mapsto ax = \sum_{i=1}^{n} a_i x_i$$

Clearly, there is a close relationship between the two, since we can get one from the other by taking a transpose. In fact, they are dual to each other. To understand the relationship, consider the level sets of the function; x is ax and how they relate to the vector at ER xx

One omission so far is the transpose of Df, in the case that  $\mathcal{F}:\mathbb{R}^n\to\mathbb{R}^m$ , and m>1. In this ase, to define;

$$\nabla S = DS^{T} = \begin{bmatrix} \frac{\partial S_{1}}{\partial x_{1}} & \frac{\partial S_{m}}{\partial x_{1}} \\ \vdots & \vdots & \vdots \\ \frac{\partial S_{1}}{\partial x_{n}} & \frac{\partial S_{m}}{\partial x_{n}} \end{bmatrix} = \begin{bmatrix} \nabla S_{1} & \cdots & \nabla S_{m} \end{bmatrix} \in \mathbb{R}^{n \times m}$$

we need to regard the matrix DS as a rector and suitably interpret it as the matrix vector indicating the direction example of steepest in crease of the vector field F. Since this is more abstract and not important for the class, we wan't go into this.

## THE VERY MARKET NO NO BORGER

The next quantity to consider is the Hissian of a scalar-velued function  $f: \mathbb{R}^n \to \mathbb{R}$ , defined as:

that is, the matrix of second partials. Note that it each mixed partial commutes:

$$\frac{\partial x_i^2}{\partial x_i^2} = \frac{\partial x_i^2}{\partial x_i^2}, \quad i \neq j,$$

then the thissian is symmetric. The geometry of the theory of optimization,

## is a world the following the work was the contraction of the contracti

Broked-

the gradient, Hussian; and Jacobian allow us to write about Taylor expansions of single and multiple-valued functions of multiple variables: First, let  $f:\mathbb{R}^n \to \mathbb{R}$ , let  $x \in \mathbb{R}^n$ , and let  $h \in \mathbb{R}^n$ . Then, the TE of f about f in the variable f is:

 $f(x+h) = f(x) + \nabla f(x)^{T}h + \frac{1}{2}h^{T}\Omega^{2}g(x)h + O(\|h\|_{2}^{3}).$ Note that the notation  $O(\cdots)$  is defined as:

 $f(x) = O(g(x)) \left[a_1 x \rightarrow x_0\right]$  if  $\lim_{x \to x_0} \frac{f(x)}{|g(x)|} < \infty$ . This is an example of Landau big-O notation. In runnerical analysis, we will nearly always use  $O(\cdots)$  to describe errors or Taylor expansion remainders, so the task tacit assumption is that  $x_0 = 0$ . Hence;

O(||h||\_2) ens a stond-in for a function which has magnitude a dominated by C. ||h||\_2 for some CZO as ||h||\_2 O.

Along the same lines, we define the R TE of a vector-valued function  $F: \mathbb{R}^n \to \mathbb{R}^m$  by:

8 (x+h) = 8 (x) + D8(x)h + O (||h||2).

Note that these are vector-valued quantities—i.e. DE(x)h
is a matrix-vector product, and OCHINIZ) is to be interpreted
as standing in for a vector-valued quantity whose magnitude
(i.e. 11.112) is dominated by a constant C > 0 times //h//z
as 1/h//2 = 0.

Throughout the class, we will fill in this picture of multivariable calculus, adding new tools as we need them.
